TITLE : STORAGE DEVICE FOR LEVEL
CORRECTION INFORMATION

CONSTITUTION: One input is selected as a reference level. An input terminal and a memory are selected with switches 8 and 24. The selected input signal is supplied to an amplifier 10 through an electronic volume control 9A and then listened to through a speaker 11. At this time, the electronic volume 9A is set to a proper sound volume. As a result, the extent of attenuation which corresponds to the input signal level is obtained. Information on the extent of attenuation is stored in the memory. Then, the firstly determined reference level is compared with another input signal to obtain the extent of attenuation adequate for the other input signal. Thus, a level difference between the sound volumes obtained by switching the input sources is eliminated.
